### week4

January 26, 2018

### 1 MIS 492 - Data Analysis and Visualization

- 1.1 Week 4
- 1.2 Data Cleansing & Transformation
- 1.2.1 Dr. Mohammad AlMarzouq

### 2 Data Cleansing & Transformation

- Is the act of cleaning and preparing the data for analysis
- It is an iterative process and requires that we explore the distributional characteristics of data
  - as we did last week
- This week we will learn the skills to slice, filter, and sort dataframes, which allows us discover problems in data and select the data that we will use for our analysis

```
In [87]: # As always, start with the following
    import pandas as pd

# Let's load the weather data
    # Notice how you can load directly from a url
    weather_df = pd.read_csv("https://github.com/vega/vega-datasets/raw/gh-pages/data/weath
```

## 3 Indexing/Slicing Dataframes

- Using square brackets
- Using loc
- Using iloc

# 4 Using Square Brackets

```
In [88]: # Labels are used to select columns
    weather_df["location"].head()
```

```
Out[88]: 0
             Seattle
              Seattle
         1
         2
              Seattle
         3
             Seattle
              Seattle
         Name: location, dtype: object
In [89]: # List or tuple of labels can also be passed to select multiple columns and their locat
         weather_df[["wind","location"]].head()
Out [89]:
           wind location
             4.7 Seattle
             4.5 Seattle
         1
           2.3 Seattle
         3
             4.7 Seattle
             6.1 Seattle
In [90]: # When using numeric slicing, it is for selecting/slicing rows
         # Works exactly like python list slicing
         weather_df[1:5]
         #Can you fetch the last 5 records?
Out[90]: location
                                 date precipitation temp_max temp_min wind weather

                                                                        2.8
                                                                              2.0
             Seattle
                                                            10.0
                                                                                      sun
         10 Seattle 2012-01-11 00:00
                                                   0.0
                                                             6.1
                                                                       -1.1
                                                                              5.1
                                                                                      sun
In [ ]: # Negative indecies don't work!
        weather_df.loc[-1]
        # Why?
In []: # you can also set the column you want like so
        weather_df.loc[1:5, ["location", "weather"]]
   Using iloc
It is exactly like loc, but uses numeric indecies
In []: weather_df.loc[1:5]
In [ ]: # Negative indicies work this time!
        weather_df.iloc[-1]
        # why?
In [ ]: # selecting columns is also numeric
        weather_df.iloc[:,0:2].head()
```

## 7 Sorting

- Sort rows based on values of column(s)
- Descending or ascending order

#### 8 Filteration

Selecting rows based on logical conditions. e.g., weather observations in New York, or observations where wind speed is higher than 10

You use conditions very similar to Python conditions in syntax, with some slight variation

(weather\_df.temp\_min < 0) &</pre>

```
(
          (weather_df.weather == "rain") |
          (weather_df.weather == "snow")
)
].head(10)
```

#### 9 Some useful functions used in filteration

- isin(values)
- isnull(), notnull()
- duplicated

You can use these in filteration conditions

In []: # Filter using method isin to find observations where whether is either rain or snow

#### 10 Data Transformation

- Operations can be performed on columns
  - Used to create new columns by combining or transforming other columns
- All values in a column will have the same operation performed on them
- When operating on two or more columns, the operations are performed on items in the same position
  - Columns must match in size

## 11 Useful methods and Operators

- Almost all the mathematical operators are available
- Useful methods to perform calculations on columns are:
  - max, min, mean, median, mode, std, var, count, sum, mod
- Method apply will accept a function that takes a single argument, and returns a value
  - The function is applied to every item in the column and a new column is created with the results
- Useful methods to clean the dataframe are:
  - dropna, drop\_duplicates, fillna

```
In []: # Calculate the mean centered value of range
        # mean centering = temp_range - mean_range
        # tells us how much the observation is different from the mean
        # name the collumn mc_range
In [ ]: # Caclulate the square of mc_range
        # name the new column mc_range_sq
In [ ]: # calculate the natural log of mc_range and use name mc_range_log
        # tip: search numpy
        # be sure to examine the data, what do you see?
        # What should you do?
        # Is fillna(0) a good idea?
In []: # based on what you know so far,
        # try to plot range, mc_range, and mc_range_sq
In []: # try to plot the distributions for the new range columns
        # hint: search for histograms
In [ ]: # try to count the number of observations where the temprature change is above average
        # can you produce a scalar value instead of a column?
        # Can you calculate the ratio?
        # Can you calculate the percentage?
In [ ]: # Calculate the average temprature for the day
        # hint: use temp_max and temp_min
In []: # plot the average temp
In []: # plot the distribution for average temp
In [ ]: # compare the distribution of average temp with mc_range
In [ ]: # find the days in which the average temprature is below zero and it is snowing
        # calculate the percentage of these days
```
